

Pagebreak edge cases (W-pagebreak fixture per D-875e4b §7d)

This fixture exercises the full set of pagebreak directive edge cases enumerated in U-976c35 and D-875e4b §6c. Each section is named with the case it covers and the expected outcome.

Section A — leading pagebreak (suppressed)

The pagebreak directive **immediately follows** this paragraph but falls AFTER it, so this section is actually section A's content. The LEADING pagebreak (if any) is the one at the very top of the document — this fixture has none, so leading suppression is exercised by fixture variants in the test code (see `pagebreak_at_document_start_is_suppressed` in `src/emitter.rs`).

Section B — single mid-document pagebreak (one `#pagebreak()` emitted)

Content above the next pagebreak.

Content below the pagebreak.

Section C — back-to-back mid-document pagebreaks (two #pagebreak() emitted)

Content immediately before the back-to-back pair.

Content immediately after — the two consecutive directives produce ONE empty page between this content and the previous, per U-976c35 “back-to-back: each directive inserts a page break ... honor it literally rather than collapsing”.

Section D — page-break alias recognized

Content above.

Content below — the hyphenated `page-break` form is also recognized per U-976c35.

Section E — case-insensitivity and whitespace-tolerance

Content above.

Content below — uppercase + extra whitespace inside the comment is tolerated.

Section F — pagebreak inside a fenced code block (NOT detected)

The directive inside a code fence is `Event::Text`, not `Event::Html` (pulldown-cmark’s CommonMark-conformant block discrimination, see D-875e4b §6g). Recognition never fires; the comment renders as literal code source.

```
<!-- pagebreak -->
```

Section G — pagebreak inside a blockquote (falls through to literal)

Per D-875e4b §1c, §6c (edge case 2): the pagebreak is non-top-level (parent `EnvFrame` is `BlockQuote`, not document body), so recognition falls through to `md_inline_html` literal pass-through. No `#pagebreak()` is emitted; no warning is fired (graceful per §6c).

Quoted content above.

```
<!-- pagebreak -->
```

Quoted content below.

Section H — pagebreak with payload form (NOT recognized)

U-976c35 strict-no-payload contract: any payload other than literal `pagebreak` / `page-break` is rejected. The following comment renders as literal source via `md_inline_html`.

```
<!-- pagebreak: top -->
```

Content after the unrecognized comment.

Section I — pagebreak inside an HTML table cell (deferred)

Per the W-pagebreak brief `done_definition #8`: this case depends on W-html-table (which introduces HTML-table parsing and thus the `TableCell` parent context for inside-cell content). Because W-html-table has not yet landed at the time of this Work, the in-table-cell case is **stubbed** here as a literal `<!-- pagebreak -->` at top-level followed by the trailing-suppression pattern. W-html-table will extend this fixture with a proper HTML-table-cell variant.

(stub — will be extended by W-html-extensions-qa per D-875e4b §7d)

Section Z — trailing pagebreak (suppressed)

The very next directive is the trailing pagebreak. Per U-976c35 “at the very end of the document: no-op”, it is silently dropped.
